- 1. Suppose you are given a magic black box that somehow answers the following decision problem *in polynomial time*:
  - INPUT: A directed graph *G* and a positive integer *L*. (The edges of *G* are not weighted, and *G* is not necessarily a dag.)
  - OUTPUT: TRUE if *G* contains a (simple) path of length *L*, and FALSE otherwise.
  - (a) Using this black box as a subroutine, describe algorithms that solves the following optimization problem *in polynomial time*:
    - INPUT: A directed graph *G*.
    - OUTPUT: The length of the longest path in *G*.
  - (b) Using this black box as a subroutine, describe algorithms that solves the following search problem *in polynomial time*:
    - INPUT: A directed graph *G*.
    - OUTPUT: The longest path in *G*

[Hint: You can use the magic box more than once.]

- 2. An *independent set* in a graph *G* is a subset *S* of the vertices of *G*, such that no two vertices in *S* are connected by an edge in *G*. Suppose you are given a magic black box that somehow answers the following decision problem *in polynomial time*:
  - INPUT: An undirected graph *G* and an integer *k*.
  - OUTPUT: TRUE if *G* has an independent set of size *k*, and FALSE otherwise.
  - (a) Using this black box as a subroutine, describe algorithms that solves the following optimization problem *in polynomial time*:
    - INPUT: An undirected graph *G*.
    - OUTPUT: The size of the largest independent set in *G*.
  - (b) Using this black box as a subroutine, describe algorithms that solves the following search problem *in polynomial time*:
    - INPUT: An undirected graph *G*.
    - OUTPUT: An independent set in G of maximum size.

[Hint: You can use the magic box more than once.]

## To think about later:

3. Formally, a *proper coloring* of a graph G = (V, E) is a function  $c: V \rightarrow \{1, 2, ..., k\}$ , for some integer k, such that  $c(u) \neq c(v)$  for all  $uv \in E$ . Less formally, a valid coloring assigns each vertex of G a color, such that every edge in G has endpoints with different colors. The *chromatic number* of a graph is the minimum number of colors in a proper coloring of G.

Suppose you are given a magic black box that somehow answers the following decision problem *in polynomial time*:

- INPUT: An undirected graph *G* and an integer *k*.
- OUTPUT: TRUE if *G* has a proper coloring with *k* colors, and FALSE otherwise.

Using this black box as a subroutine, describe an algorithm that solves the following *coloring problem in polynomial time*:

- INPUT: An undirected graph *G*.
- OUTPUT: A valid coloring of *G* using the minimum possible number of colors.

[*Hint:* You can use the magic box more than once. The input to the magic box is a graph and **only** a graph, meaning **only** vertices and edges.]

- 4. Suppose you are given a magic black box that somehow answers the following decision problem in *polynomial time*:
  - INPUT: A boolean circuit *K* with *n* inputs and one output.
  - OUTPUT: TRUE if there are input values  $x_1, x_2, ..., x_n \in \{\text{TRUE}, \text{FALSE}\}$  that make *K* output TRUE, and FALSE otherwise.

Using this black box as a subroutine, describe an algorithm that solves the following related search problem *in polynomial time*:

- INPUT: A boolean circuit *K* with *n* inputs and one output.
- OUTPUT: Input values x<sub>1</sub>, x<sub>2</sub>,..., x<sub>n</sub> ∈ {TRUE, FALSE} that make K output TRUE, or NONE if there are no such inputs.

[Hint: You can use the magic box more than once.]
